A-1

BACKGROUND

The Naval Ocean Systems Center (NOSC) sponsored the National Climatic Data Center, Asheville, North Carolina to produce a subset analysis of its Standard Tape Deck Family 11 (STD-11) database. The STD-11 database consists of over 150 years of worldwide surface meteorological observations such as wind speed, present weather, air temperature, and other meteorological quantities. These observations were assembled from ship logs, ship weather reporting forms, published ship observations, automatic buoys, teletype reports, and card decks purchased from foreign meteorological services.

The subset analysis, known as DUCT63, covers 293 Marsden squares and spans 15 years of surface observations from 1970 through 1984. A Marsden square is a region of the earth's surface defined by a grid of 10 degrees latitude by 10 degrees longitude and is assigned a unique identification number. Figure 1 shows the location and the numerical assignment of all Marsden squares. For example, Marsden square 1 is defined as the region bounded by the prime meridian to 10 degrees west longitude and from the equator to 10 degrees north latitude. Not all of the 648 possible Marsden squares are included in the DUCT63 analysis for two reasons. First, the analysis is specifically concerned with the maritime environment. Marsden squares not containing a region of ocean are excluded from the data. Second, a requirement of at least 100 valid observations per month was imposed to reduce the effects of any spurious meteorological measurements on the distributions. Figure 1 shows the location of the Marsden squares contained within the DUCT 63 analysis as the region enclosed by the heavy border.

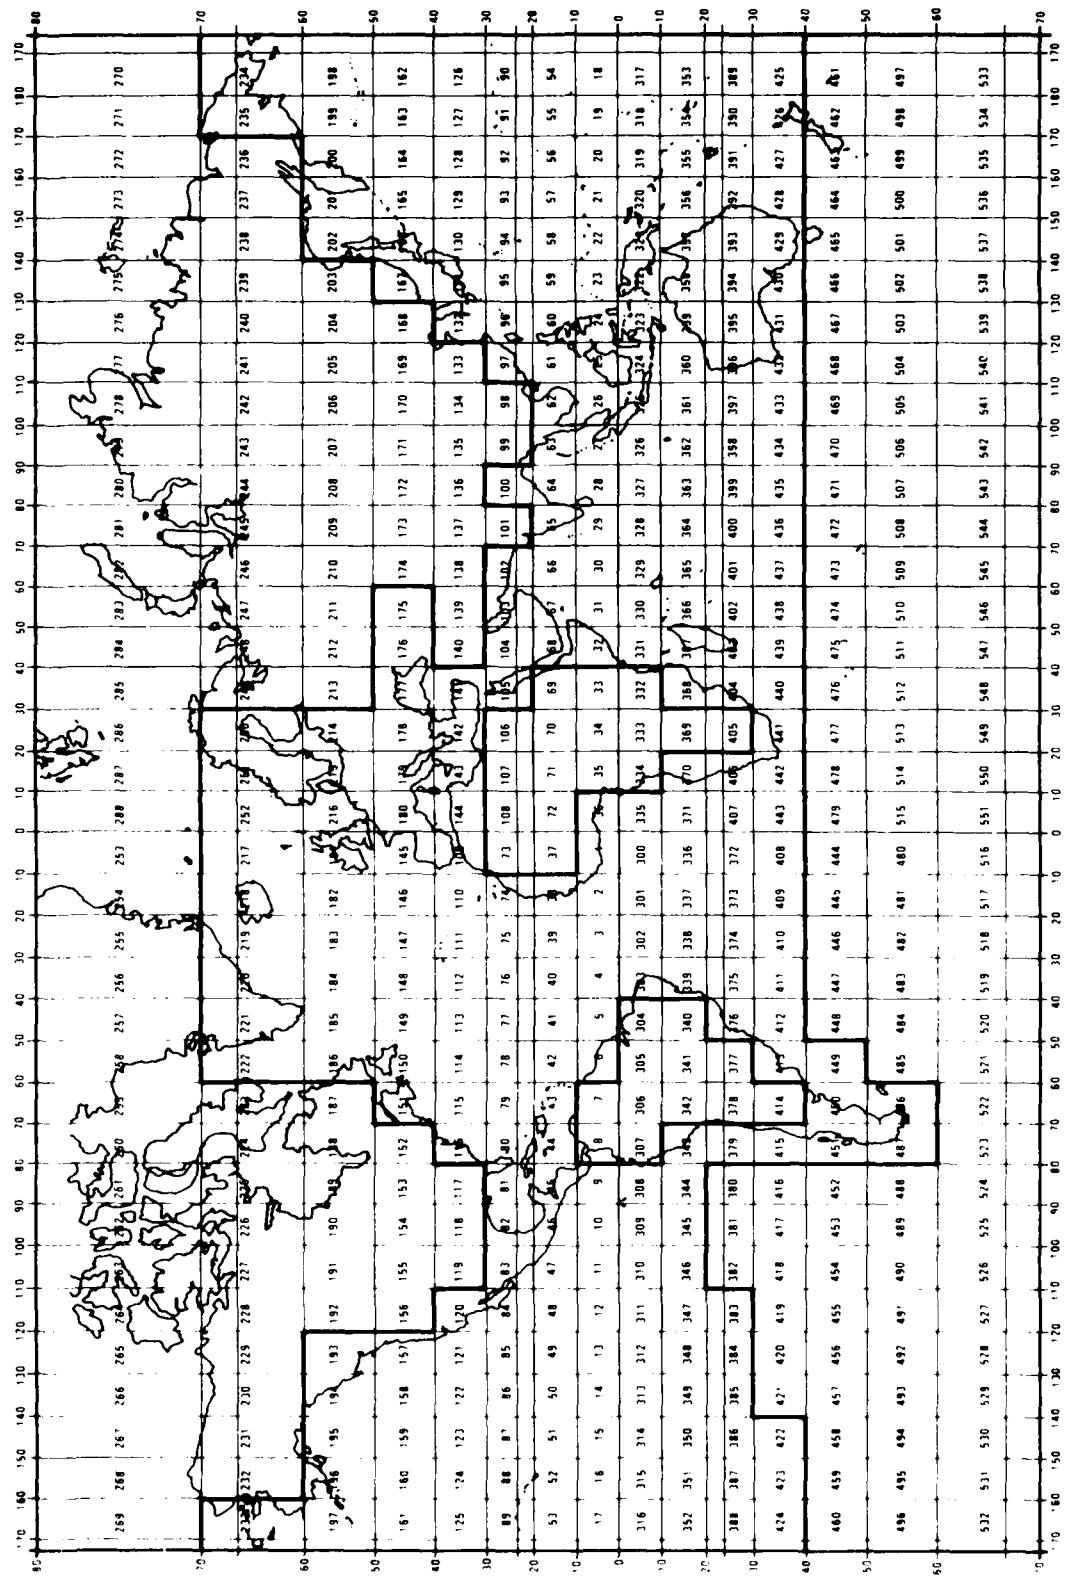

Figure 1. Geographical location of Marsden square data in the DUCT63 analysis.

GENERAL DUCT63 DATABASE DESCRIPTION

The DUCT63 analysis contains distributions of meteorological quantities and surface-to-surface attenuation rates for frequencies of 35 and 94 GHz. These distributions are expressed as tables of either a probability or a percentage of time that the quantity is observed within a specified range. The distributions include diurnal effects where day or daytime categories imply a positive solar angle within the Marsden square at the time of the meteorological observation. Night categories are times of observation between one hour after the local sunset and one hour before the local sunrise. Observations taken in the interval between the day and night categories are excluded from the data set.

There are two forms of distributions: a probability (or percent of time) distribution for a specific quantity (e.g., wind speed) and a joint probability distribution of two quantities. The latter form, also called a cross distribution, is specifically designed for use by NOSC in its research efforts.

Each page of tables is labeled with the Marsden square number and the period of record (POR). The POR is expressed as QQRR-SSTT where QQ is the starting year, RR is the starting month, SS is the ending year and TT is the ending month. Generally, the POR is 7001-8412 indicating that the data is comprised of observations taken between January 1970 and December 1984. The probability distributions of specific quantities include the mean value of the quantity and the number of valid observations that the distribution is derived from. The cross distributions indicate the number of valid observations.

DUCT63 DATABASE QUANTITIES

The following quantities are distributed within the DUCT63 analysis and are tabularized on microfiche in the same order:

- Paulus evaporation duct height (meters)
- Paulus evaporation duct height crossed with Jeske duct height
- Wind speed (meters per second)
- Absolute humidity (grams per cubic meter)
- Modified air-sea temperature difference (degree C)
- Rain rate (scaled millimeters per hour)
- Attenuation rate (gaseous) at 35 GHz (scaled dB/km)
- Attenuation rate (gaseous) at 94 GHz (scaled dB/km)
- Attenuation rate (total) at 35 GHz (scaled dB/km)
- Attenuation rate (total) at 94 GHz (scaled dB/km)
- Paulus evaporation duct height crossed with wind speed

Parameters such as evaporation duct height and the modified air-sea temperature difference do not have an effect on the validity of the data. Details of the specific quantities and distributions have been described in the following paragraphs.

PAULUS EVAPORATION DUCT HEIGHT

The Paulus formulation of evaporation duct height calculations (reference 1) is a modification to the classical Jeske method (reference 2). The major difference in the approaches is that the Paulus technique attempts to account for inaccuracies in air temperature observations which are caused by thermal influence of the ship. The distributions of duct height are in 2-meter intervals from 0 to 40 meters and two additional categories - duct heights greater than 40 meters and duct heights that are not calculable (undefined). Figures 2 through 4 are the results from Marsden square 1. Note the label indicating the mean sub square (mean sub sq) 25. Marsden squares are subdivided into 1-degree sub squares and this label (25) shows the mean location of all of the observations within the analysis for this square. Under each distribution are the values of the mean height and the first through third quartile. From figure 2, a duct height in the interval of 10 to 12 meters for a January day is observed 14.4 percent of the time (the probability is 0.144). The mean height of the duct for a March night period is 11.0 meters. There were 2,229 valid observations found in constructing the distribution for the April day period.

PAULUS EVAPORATION DUCT HEIGHT CROSSED WITH JESKE DUCT HEIGHT

Figures 5 through 7 tabulate the joint probability of a duct height computed by the Paulus and Jeske methods for Marsden square 1. The distributions are in 2 meter intervals as described above. To obtain a reasonable format of the tables, the true probability is scaled by a factor 10,000. For example, the joint probability of finding a Paulus and Jeske duct height in the interval of 10 to 12 meters in Marsden square 1 during daylight hours is given in figure 5 as 0.0749. Also, the total number of valid observations used to construct figure 5 is given at the bottom of the table and is 23,552.

WIND SPEED

Figures 8 through 10 show the distributions of wind speed, in meters per second (m/s), for Marsden square 1. From figure 8, the mean wind speed during January night conditions is 3.7 m/s which is derived from 1,739 valid observations. A wind speed between 5 and 6 m/s is observed 12.2 percent of the time during February daylight hours.

ABSOLUTE HUMIDITY

Figures 11 through 13 show examples of absolute humidity distributions. The categories are in grams per cubic meter (g m^{-3}). During March daylight hours, the mean absolute humidity is 22.6 g m^{-3} . Absolute humidity is observed 48.6 percent of the time for the interval 21 to 23 g m^{-3} .

MODIFIED AIR-SEA TEMPERATURE DIFFERENCE

Reference 1 defines the modified air-sea temperature difference. Its purpose for inclusion within the DUC163 database is to aid NOSC research efforts in the climatological description of evaporation duct heights. Figures 14 through 16 show examples of the distribution format.

RAIN RATE

Figures 17 through 19 show rain-rate distributions for Marsden square 1. Rain rate is not a directly reported quantity in the STD-11 database. Rather, it is computed from the present weather code by techniques developed by Goroch (reference 3). The categories of distribution are tabularized scaled by a factor of 100. From figure 17, the rain rate is reported to occur 0.4 percent of the time in the range of 1.26 to 1.51 millimeters per hour (mm/hr) during a January day time period. The mean rain rate for a March day time period is reported as 0.067 mm/hr and is derived from 1,712 reports of present weather.

GASEOUS ATTENUATION RATE AT 35 GHz

Figures 20 through 22 are the distributions of gaseous attenuation rate at a frequency of 35 GHz for Marsden square 1. This quantity is derived from observations of air temperature, relative humidity, and visibility.

The reported visibility is used to calculate a value of the liquid water content based on the work of Johnson reported by Cook (reference 4). Methods described by Liebe (reference 5) are used to calculate the attenuation rate. Since the meteorological data is surface data, the attenuation rate is valid only for surface-to-surface propagation. It is not applicable for use with slant paths.

In the tables, the labeled attenuation rates are scaled by a factor of 1,000. From figure 20, the mean attenuation rate for a January night is 0.2593 dB/km. The distribution indicates that an attenuation rate between 0.226 and 0.251 dB/km is observed to occur 26.7 percent of the time.

GASEOUS ATTENUATION RATE AT 94 GHz

The description above applies to the tables shown in figures 23 through 25 with two exceptions. First, the frequency is 94 GHz and second, the scaling factor is 100, not 1,000 as above. From figure 23, the surface-to-surface attenuation rate (at 94 GHz) is observed to fall between 1.01 and 1.26 dB/km 58.9 percent of the time during a February night period. The mean value is 1.24 dB/km.

TOTAL ATTENUATION AT 35 GHz

The major difference between the attenuation rate described for this quantity and the attenuation rate described above is that the total attenuation includes the effects of rain rate. The contributions from rain rate are modeled after the work of Falcone (reference 6).

Figures 26 through 28 are the results for Marsden square 1. From figure 26, the mean attenuation rate for an April day period is 0.3028 dB/km (the categories are scaled by a factor of 1,000). The distribution for the same period indicates an attenuation rate between 0.251 and 0.276 dB/km is observed 50.7 percent of the time.

TOTAL ATTENUATION AT 94 GHz

The comments of the preceding section are directly applicable for the total attenuation rate at 94 GHz. Again, it should be stressed that the meteorological data are observed at the surface and the attenuation rates described are strictly applicable to a surface-to-surface path. That is, the data are not applicable to a slant path.

Figures 29 through 31 present tables of the total attenuation rate at a frequency of 94 GHz for Marsden square 1. From figure 29, the attenuation rate for an April day period is observed 53.1 percent of the time in the interval 1.01 to 1.26 dB/km. The mean attenuation rate is 1.408 dB/km for the same period.

PAULUS DUCT HEIGHT CROSSED WITH WIND SPEED

Similar to the cross distribution discussed previously, figures 32 through 34 present the cross distribution of the Paulus duct height and wind speed. These tables are designed primarily for use by NOSC in the determination of evaporation ducting.
